Detect Caps Lock Is On
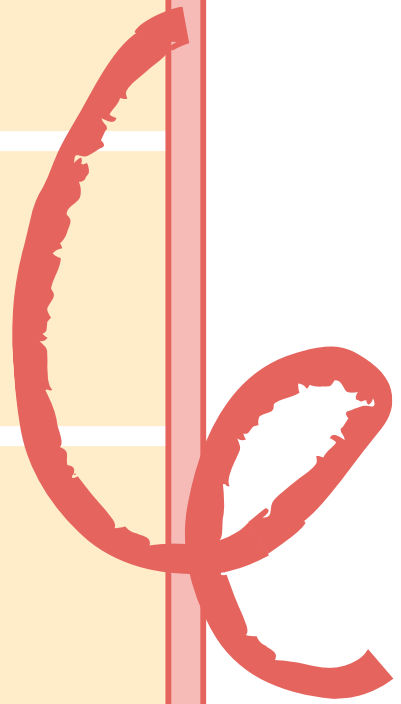

To check if the caps lock is on, you use the `getModifierState()` method of the `KeyboardEvent` object:

```
const capslockIsOn = event.getModifierState(modifier);
```

The `getModifierState()` method returns `true` if a `modifier` is active; otherwise, it returns `false`.

The `event.getModifierState('CapsLock')` can be used to detect if the caps lock is on.

Suppose you have a password field like this:

```html
<input type="password" name="password" id="password" placeholder="Enter a password
  <div class="message"></div>
```

The following shows a warning message if you turn on the caps lock and type the password:

```javascript
const password = document.querySelector('#password');
const message = document.querySelector('.message');

password.addEventListener('keyup', function (e) {
    if (e.getModifierState('CapsLock')) {
        message.textContent = 'Caps lock is on';
    } else {
        message.textContent = '';
    }
});
```
